One-Stop Access To Course Information

- **Course website**: One-stop access to all course information.
  
  http://www2.cs.sfu.ca/CourseCentral/120/liaqata/WebSite/index.html

- Course Outline
- Exam Schedule
- Python Info
- **CourSys/Canvas** link
- Learning Outcomes
- Office Hours
- Textbook links
- and more...
- Grading Scheme
- Lab/Tutorial Info
- Assignments

- **Canvas**: Discussions forum - https://canvas.sfu.ca/courses/39187

- **CourSys**: Assignments submission, grades - www.coursys.sfu.ca

Liaqat Ali, Summer 2018.
How to Learn in This Course?

Attend Lectures & Labs
Read / review Textbook/Slides/Notes
Reflect and ask Questions
Organize – your learning activities on weekly basis, and finally...
Write Code, Write Code, and Write Code.
Deliverables

1. Deliverables are due by the given date and time.
2. For the course, we are using IDLE to write and run our Python code.
3. You can use the CSIL lab computers outside your lab hours.
4. Plan ahead your assignments and other deliverables. Computer crash, network problems etc. are not acceptable excuses for delays in deliverables.
5. You may use online Python interpreters for running and testing your codes, such as:  
   https://repl.it/languages/Python3
Labs

1. Each lab has an assigned TA.
2. Attend your assigned lab and show your work to your TA for the participation marks.
3. Class enrolments and lab swaps are closed now.
Course Topics

1. General introduction
2. Algorithms, flow charts and pseudocode
3. **Procedural programming in Python**
4. Data types and control structures
5. Fundamental algorithms
6. Binary encodings
7. Basics of computability and complexity
8. Basics of Recursion
9. Subject to time availability:
   - Basics of Data File management
Today’s Topics

1. Operators
   i. Arithmetic Operators (+, -, *, /)
   ii. Comparison operators (<, >, <=, >=, ==, !=)
   iii. Binary and unary operators
   iv. Logical Operators (and, or, not)

2. Variables / Variable Names

3. Assignment Statements

4. Statement
Review

Can you name or describe the following?

In Python...

1. 5 is ____
2. total is _____
3. + is ____
4. == is a
5. a + b is ____
6. midterm > 95 is ____

Liaqat Ali, Summer 2018.
Review: 2

In Python:

1. \( x - 5 \) is _____
2. \( X \neq 5 \) is _____
3. % is _____
4. \( (a \geq 60) \) is a Boolean expression
5. \( (a < 70) \) is _____
6. \( (a \geq 60) \) and \( (a < 70) \) is _____
Binary and Unary Operators

- **Binary operator**: The operator that requires **two** operands.
  - To add we need two numbers or two operands, so + is a binary operator. For example, **10 + 6**. Other examples:
    - All arithmetic operators. _______________________________
    - All the conditional operators ___________________________
- **Unary operator**: The operator that requires only **one** operand.
Logical Operators

Liaqat Ali, Summer 2018.
Logical Operators

• The symbols **and**, **or**, and **not** are called **logical operators**.

• We use **and** and **or** logical operators to create **compound** Boolean expressions.

• We use **not** logical operator to **reverse** the result of its operand.  
  - `not(a>70)`

• A compound Boolean expression returns a **True** or **False** result.

Liaqat Ali, Summer 2018.
Logical Operators: In Compute Grade Example

```python
midterm = 0
final = 0

midterm = input("Enter midterm:")
final = input("Enter final:")

total = float(midterm) + float(final)

if total>=95: print("A+")
elif total>=90 and total<95: print("A")
elif total>=85 and total<90: print("A-")
elif total>=80 and total<85: print("B+")
elif total>=75 and total<80: print("B")
elif total>=70 and total<75: print("B-")
elif total>=65 and total<70: print("C+")
elif total>=60 and total<65: print("C")
elif total>=55 and total<60: print("C-")
elif total>=50 and total<55: print("D")
else: print("F")
```

Logical operators
Logical Operator: **and**

- **and**: The **and** is a *binary* logical operator that connects two Boolean expressions into one compound expression.
  - The result of **and** compound binary expression is **true** when **all** the sub expressions are **true**.
  - For example, the result of a compound Boolean expression
    
    |                  |                  |
    |------------------|------------------|
    |                  |                  |
    |                  |                  |
    

Logical Operator: *and* Truth Table

- We can simplify the and results, or decision structure, using a table. We call it a Truth Table.
- Truth table for the *and* operator:

<table>
<thead>
<tr>
<th>Expression 1</th>
<th>Expression 2</th>
<th>Expression 1 and expression 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>marks &gt;= 90</td>
<td>marks &lt; 95</td>
<td>marks &gt;= 90 and marks &lt; 95 (A)</td>
</tr>
</tbody>
</table>
Logical Operator: *or*

- **or**: The *or* is a *binary* logical operator that connects two Boolean expressions into one compound expression.
  - The result of *or* compound binary expression is *true* when *either* of the sub expressions is *true*.
  - For example, the result of a compound Boolean expression

  - gpa > 2.5 Boolean expression is true, or
  - height > =7 Boolean expression is true.
Logical Operator: *or* Truth Table

- We can simplify the and results, or decision structure, using a table. We call it a **Truth Table**.
- Truth table for the **or** operator:

<table>
<thead>
<tr>
<th>Expression 1</th>
<th>Expression 2</th>
<th>Expression 1 <strong>and</strong> expression 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>gpa &gt;= 2.5</td>
<td>height &gt;= 7</td>
<td>gpa &gt;= 2.5 <em>or</em> height &gt;= 7 (<strong>Admit</strong>)</td>
</tr>
</tbody>
</table>
Short-Circuit Evaluation (I would call it a smart evaluation)

- **Short-circuit** is deciding the value of a compound Boolean expression after evaluating only one sub expression.
- Performed by the **and** and **or** operators.
- For **and** operator: If left operand is **false**, compound expression is false. Otherwise, evaluate right operand.
- For **or** operator: If left operand is **true**, compound expression is true. Otherwise, evaluate right operand.
Logical Operator: *not* its and Truth Table

- **not**: It reverses the logical value of the Boolean expression.
  - It turns a *true* into *false*, and a *false* into a *true*.
  - It takes only one operand. So *or* is a unary operator.
  - It is recommended to place parentheses around a Boolean expression to clarify to what you are applying the not operator.

  - **not** *(gpa >= 2.5)*

<table>
<thead>
<tr>
<th>Expression</th>
<th>Not(expression)</th>
</tr>
</thead>
<tbody>
<tr>
<td>True</td>
<td>False</td>
</tr>
<tr>
<td>False</td>
<td>True</td>
</tr>
</tbody>
</table>
Variables / Assignment Statement
Variables

- **Variable** is a name that represents a value stored in the computer memory (RAM).
  - We store data in computer memory via variable names.
  - We access and manipulate data in memory via variables.
  - Examples: `marks`, `midterm`, `sum`, or `total`.

- **Assignment Statement** assigns a value to a variable. (*Variable that receive value should be on left.*)
  - `midterm = 50`
  - `sum = 100`
  - `name = "Joe"`

- You can only use a variable if a value is assigned to it.
Variable Naming Rules

• Rules for naming variables in Python:
  ▫ Variable name cannot be a Python key word, like input, print, if
  ▫ Variable name cannot contain spaces.
    •
  ▫ First character must be a letter or an underscore.
    •
  ▫ After first character may use letters, digits, or underscores.
    •
  ▫ Variable names are case sensitive.
    •
• Variable name should reflect its use.
**Statement**

- **Statement** is a unit of code that has an effect, like creating a variable or displaying a value.

- For example,

  \[ n = 17 \] is a statement.

  \[ \text{print}(n) = 17 \] is a statement.

  \[ \text{marks} = \text{input}(\text{"Enter marks: "}) \] is a statement.
