Introduction to Java

Chapters 1 and 2
The Java Language – Section 1.1
Data & Expressions – Sections 2.1 – 2.5

Instructor: Scott Kristjanson
CMPT 125/125
SFU Burnaby, Fall 2013
Scope

Introduce the Java programming language
- Program, Class, and Methods
- The Use of White Space and Comments
- Strings, Concatenation, and Escape Sequences
- Declaration and Use of Variables
- Java Primitive Data Types
- Syntax and Processing of Expressions
- Mechanisms for Data Conversion
Java

A computer is made up of hardware and software

- **hardware** – the physical, tangible pieces that support the computing effort
- **Program** – a series of instructions that the hardware executes

Programs are sometimes called **Applications**

**Software**

- consists of programs and the data those programs use
- Data includes files on disk such as pictures, templates, and databases
- Data can also be input from a user, the internet, or from devices

Java

A *programming language* specifies the words and symbols that we can use to write a program.

A programming language employs a set of rules that dictate how the words and symbols can be put together to form valid *program statements* – this is called *Syntax*.

The Java programming language was created by Sun Microsystems, Inc.

It was introduced in 1995 and its popularity grew quickly, it is now the #1 most widely used programming language\(^2\).
The Java Programming Language

In the Java programming language:

- a program is made up of one or more classes
- a class contains one or more methods
- a method contains program statements

These terms will be explored in detail throughout the course.

A Java application always contains a method called main
A Java Program

```java
public class MyProgram {
    // class header
    // class body
    // Comments can be placed almost anywhere
}
```
A Java Program

// comments about the class
public class MyProgram
{
    // comments about the method
    public static void main(String[] args)
    {
        method body
    }
}
Comments

Comments should be included to explain the purpose of the program and describe processing.

Do not explain the obvious, explain the intent of the code at a higher level.

They do not affect how a program works.

Java comments can take three forms:

// this comment runs to the end of the line

/*  this comment runs to the terminating symbol, even across line breaks */

/** this is a javadoc comment */
A Very Simple Java Program

```java
//******************************************************************
// Lincoln.java Java Foundations
// Demonstrates the basic structure of a Java application.
//******************************************************************

class Lincoln {
    // Prints a presidential quote.
    public static void main(String[] args) {
        System.out.println("A quote by Abraham Lincoln:");
        System.out.println("Whatever you are, be a good one.");
    }
}
```

**Output:**

A quote by Abraham Lincoln:
Whatever you are, be a good one.
Identifiers

Identifiers are the words a programmer uses in a program to name things

• can be made up of letters, digits, the underscore character ( _ ), and the dollar sign
• cannot begin with a digit

Java is case sensitive

• Total, total, and TOTAL are different identifiers

By convention, programmers use different case styles for different types of identifiers, such as

• title case for class names - Lincoln
• upper case for constants - MAXIMUM
Identifiers

Sometimes we choose identifiers ourselves when writing a program (such as `Lincoln`)

Sometimes we are using another programmer's code, so we use the identifiers that he or she chose (such as `println`)

Often we use special identifiers called *reserved words* that already have a predefined meaning in the language

A reserved word cannot be used in any other way
**Reserved Words**

Java reserved words:

<table>
<thead>
<tr>
<th>abstract</th>
<th>default</th>
<th>goto*</th>
<th>package</th>
<th>this</th>
</tr>
</thead>
<tbody>
<tr>
<td>assert</td>
<td>do</td>
<td>if</td>

White Space

In Java:

• Spaces, blank lines, and tabs are called *white space*
• White space is used to separate words and symbols in a program
• A valid Java program can be formatted many ways
• Extra white space and indenting is ignored by the Java compiler
• Proper use of White Space is important – for *people* to understand it
• Programs should be formatted to enhance readability, using consistent indentation
A Poorly formatted version of Lincoln

Java may not care about format, but your reader does…
Use White Space to highlight program structure
Unclear White Space will lose marks for readability in your assignments!

//*****************************************************************
// Lincoln2.java       Java Foundations
//// Demonstrates a poorly formatted, though valid, program.
//*****************************************************************

public class Lincoln2{
public static void main(String[] args){
System.out.println("A quote by Abraham Lincoln:");
System.out.println("Whatever you are, be a good one.");}}
This use of White Space is horribly unclear and could get you ZERO on an assignment!

```java
// Lincoln3.java       Java Foundations
// // Demonstrates another valid program that is poorly formatted.
//*****************************************************************************
public       class
Lincoln3
{
    public
        static
            void
main
            (
String
                []
            args
                    )
        {
            System.out.println
                ("A quote by Abraham Lincoln:"          )
            ;
            System.out.println
                ("Whatever you are, be a good one."
            )
        ;
    }
}         
```
Chapter 2

Data & Expressions – Sections 2.1 – 2.5
Scope

Character strings and concatenation
Escape sequences
Declaring and using variables
Java primitive types
Expressions
Data conversions
Character Strings

A string of characters can be represented as a *string literal* by putting double quotes around it.

Examples:

"This is a string literal."
"123 Main Street"
"X"

Every character string is an object in Java, defined by the `String` class.

Every string literal represents a `String` object.
The println Method

In the Lincoln program, we invoked the **println** method to print a character string.

The **System.out** object represents a destination (the monitor) to which we can send output.
The print Method

The `System.out` object provides another service as well.

The `print` method is similar to the `println` method, except that it does not advance to the next line.

Therefore anything printed after a `print` statement will appear on the same line.

```java
public class Countdown {
    public static void main(String[] args) {
        System.out.print("Three... ");
        System.out.print("Two... ");
        System.out.print("One... ");
        System.out.print("Zero... ");

        System.out.println("Liftoff!"); // appears on first output line
        System.out.println("Houston, we have a problem.");
    }
}
```

Output:

```
Three... Two... One... Zero... Liftoff!
Houston, we have a problem.
```

Scott Kristjanson – CMPT 125/126 – SFU
String Concatenation

The *string concatenation operator* (+) is used to append one string to the end of another

"Peanut butter " + "and jelly"

It can also be used to append a number to a string

A string literal cannot be broken across two lines in a program
String Concatenation Example

```java
//********************************************************************
// Facts.java      Java Foundations
// Demonstrates the use of the string concatenation operator and the
// automatic conversion of an integer to a string.
//********************************************************************
public class Facts
{
    //-----------------------------------------------------------------
    // Prints various facts.
    //-----------------------------------------------------------------
    public static void main(String[] args)
    {
        // Strings can be concatenated into one long string
        System.out.println("We present the following facts for your " + "extracurricular edification:");
        System.out.println();

        // A string can contain numeric digits
        System.out.println("Letters in the Hawaiian alphabet: 12");
        // A numeric value can be concatenated to a string
        System.out.println("Dialing code for Antarctica: " + 672);
        System.out.println("Year in which Leonardo da Vinci invented " + "the parachute: " + 1515);
        System.out.println("Speed of ketchup: " + 40 + " km per year");
    }
}
```

We present the following facts for your extracurricular edification:
Letters in the Hawaiian alphabet: 12
Dialing code for Antarctica: 672
Year in which Leonardo da Vinci invented the parachute: 1515
Speed of ketchup: 40 km per year
String Concatenation versus Addition

The + operator is also used for arithmetic addition
The function performed depends on the type of the operands
If both operands are strings, or if one is a string and one is a number, it performs string concatenation.
If both operands are numeric, it adds them.
The + operator is evaluated left to right, but parentheses can force the order

```java
public class Addition {
    //---------------------------------------------------
    // Concatenates and adds two numbers and prints the results.
    //---------------------------------------------------
    public static void main(String[] args) {
        System.out.println("24 and 45 concatenated: " + 24 + 45);
        System.out.println("24 and 45 added: " + (24 + 45));
    }
}
```

24 and 45 concatenated: 2445
24 and 45 added: 69
Escape Sequences

What if we wanted to print a the quote character?

The following line would confuse the compiler because it would interpret the second quote as the end of the string

```java
System.out.println("I said "Hello" to you.");
```

An *escape sequence* is a series of characters that represents a special character

An escape sequence begins with a backslash character (`\`)  

```java
System.out.println("I said \"Hello\" to you.");
```

I said "Hello" to you.
Escape Sequences

Some Java escape sequences:

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\b</td>
<td>backspace</td>
</tr>
<tr>
<td>\t</td>
<td>tab</td>
</tr>
<tr>
<td>\n</td>
<td>newline</td>
</tr>
<tr>
<td>\r</td>
<td>carriage return</td>
</tr>
<tr>
<td>&quot;</td>
<td>double quote</td>
</tr>
<tr>
<td>'</td>
<td>single quote</td>
</tr>
<tr>
<td>\</td>
<td>backslash</td>
</tr>
</tbody>
</table>
Variables

A *variable* is a name for a location in memory

Before it can be used, a variable must be *declared* by specifying its name and the type of information that it will hold

```java
int total;
int count, temp, result;
```

Multiple variables can be created in one declaration
Variables

A variable can be given an initial value in the declaration

When a variable is used in a program, its current value is used

```java
public class PianoKeys {
    public static void main(String[] args)
    {
        int keys = 88;
        System.out.println("A piano has " + keys + " keys.");
    }
}
```

A piano has 88 keys.
An *assignment statement* changes the value of a variable.
The assignment operator is the = sign.

```
total = 55;
```

The expression on the right is evaluated and the result is stored in the variable on the left.

The value that was in `total` is overwritten.

You can only assign a value to a variable that is consistent with the variable's declared type.
Assignment

The right-hand side could be an expression

The expression on the right is completely evaluated and the result is stored in the variable identified on the left

```java
height = height + gap;
```
Constants

A *constant* is an identifier that is similar to a variable except that it holds the same value during its entire existence.

As the name implies, it is constant, not variable.

The compiler will issue an error if you try to change the value of a constant.

In Java, we use the `final` modifier to declare a constant.

```java
final int MIN_HEIGHT = 69;
```
Constants are useful for three important reasons

• First, they give meaning to otherwise unclear literal values
  • For example, `MAX_LOAD` means more than the literal 250

• Second, they facilitate program maintenance
  • If a constant is used in multiple places, its value need only be updated in one place

• Third, they formally establish that a value should not change, avoiding inadvertent errors by other programmers
Primitive Data Types

There are eight primitive data types in Java

Four of them represent integers

- byte, short, int, long

Two of them represent floating point numbers

- float, double

One of them represents characters

- char

And one of them represents boolean values

- boolean
# Numeric Types

The difference between the various numeric primitive types is their size, and therefore the values they can store:

<table>
<thead>
<tr>
<th>Type</th>
<th>Storage</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>8 bits</td>
<td>-128</td>
<td>127</td>
</tr>
<tr>
<td>short</td>
<td>16 bits</td>
<td>-32,768</td>
<td>32,767</td>
</tr>
<tr>
<td>int</td>
<td>32 bits</td>
<td>-2,147,483,648</td>
<td>2,147,483,647</td>
</tr>
<tr>
<td>long</td>
<td>64 bits</td>
<td>-9,223,372,036,854,775,808</td>
<td>9,223,372,036,854,775,807</td>
</tr>
<tr>
<td>float</td>
<td>32 bits</td>
<td>Approximately -3.4E+38 with 7 significant digits</td>
<td>Approximately 3.4E+38 with 7 significant digits</td>
</tr>
<tr>
<td>double</td>
<td>64 bits</td>
<td>Approximately -1.7E+308 with 15 significant digits</td>
<td>Approximately 1.7E+308 with 15 significant digits</td>
</tr>
</tbody>
</table>
Characters

A `char` variable stores a single character. Character literals are delimited by single quotes:

```
'a'   'X'    '7'    '$'    ','    '\n'
```

Example declarations

```java
char topGrade = 'A';
char terminator = ';', separator = ' ';
```

Note the distinction between a primitive character variable, which holds only one character, and a `String` object, which can hold multiple characters.
Character Sets

A character set is an ordered list of characters, with each character corresponding to a unique number.

A char variable in Java can store any character from the Unicode character set.

The Unicode character set uses sixteen bits per character. It is an international character set, containing symbols and characters from many world languages.
Characters

The *ASCII character set* is older and smaller than Unicode

The ASCII characters are a subset of the Unicode character set, including:

- **uppercase letters**: A, B, C, ...
- **lowercase letters**: a, b, c, ...
- **punctuation**: period, semi-colon, ...
- **digits**: 0, 1, 2, ...
- **special symbols**: &, |, \, ...
- **control characters**: carriage return, tab, ...
Booleans

A **boolean** value represents a true or false condition

The reserved words **true** and **false** are the only valid values for a boolean type

```java
boolean done = false;
```

A **boolean** variable can also be used to represent any two states, such as a light bulb being on or off

```java
boolean Bulb_On = false;
```
Expressions

An expression is a combination of one or more operators and operands.

Arithmetic expressions compute numeric results and make use of the arithmetic operators:

- Addition (+)
- Subtraction (−)
- Multiplication (∗)
- Division (/)
- Remainder (%)

If either or both operands used by an arithmetic operator are floating point, then the result is a floating point number.
Division and Remainder

If both operands to the division operator (/) are integers, the result is an integer (the fractional part is discarded)

\[ 14 \div 3 \quad \text{equals} \quad 4 \]

\[ 8 \div 12 \quad \text{equals} \quad 0 \]

The remainder operator (%) returns the remainder after dividing the second operand into the first

\[ 14 \% 3 \quad \text{equals} \quad 2 \]
Operator Precedence

Operators can be combined into complex expressions
\[ \text{result} = \text{total} + \text{count} / \text{max} - \text{offset}; \]

Operators have a well-defined precedence which determines the order in which they are evaluated.

Multiplication, division, and remainder are evaluated prior to addition, subtraction, and string concatenation.

Arithmetic operators with the same precedence are evaluated from left to right, but parentheses can be used to force the evaluation order.
Operator Precedence

What is the order of evaluation in the following expressions?

\[ a + b + c + d + e \]
\[ a + b * c - d / e \]
\[ a / (b + c) - d % e \]
\[ a / (b * (c + (d - e))) \]
Operator Precedence

What is the order of evaluation in the following expressions?

\[ a + b + c + d + e \]
\[ a + b \times c - d / e \]
\[ a / (b + c) - d \% e \]
\[ a / (b \times (c + (d - e))) \]
Expression Trees

The evaluation of a particular expression can be shown using an *expression tree*. The operators lower in the tree have higher precedence for that expression.

![Expression Tree Diagram]

Evaluating: \( a + \frac{(b - c)}{d} \)

Assignment Revisited

The assignment operator has a lower precedence than the arithmetic operators

First the expression on the right hand side of the = operator is evaluated

\[
\text{answer} = \frac{\text{sum}}{4} + \text{MAX} \times \text{lowest};
\]

Then the result is stored in the variable on the left hand side
Assignment Revisited

The right and left hand sides of an assignment statement can contain the same variable

First, one is added to the original value of count

\[ \text{count} = \text{count} + 1; \]

Then the result is stored back into count (overwriting the original value)
Increment and Decrement Operators

The increment and decrement operators use only one operand.

The *increment operator* (++*) adds one to its operand.
The *decrement operator* (--) subtracts one from its operand.

The statement

```java
count++;  
```

is functionally equivalent to

```java
count = count + 1;
```
Increment and Decrement Operators

The increment and decrement operators can be applied in two forms:

*Postfix:*

```
counter++; // Increment counter after returning its value
```

*Prefix:*

```
++counter; // Increment counter before returning its value
```

Because of their subtleties, the increment and decrement operators should be used with care until you have more experience with them.

When used as part of a larger expression, the two forms can have very different effects.

What is the output from this code fragment?

```
int counter = 1;
System.out.println("counter = " + counter++ + ++counter);
```

**Why 13? Does counter now equal 13?**

Of course not! counter’s final value is 3.
Assignment Operators

Often we perform an operation on a variable, and then store the result back into that variable.

Java provides assignment operators to simplify that process.

For example, the statement

```java
num += count;
```

is equivalent to

```java
num = num + count;
```
# Assignment Operators

There are many assignment operators in Java, including the following:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Example</th>
<th>Equivalent To</th>
</tr>
</thead>
<tbody>
<tr>
<td>+=</td>
<td>x += y</td>
<td>x = x + y</td>
</tr>
<tr>
<td>-=</td>
<td>x -= y</td>
<td>x = x - y</td>
</tr>
<tr>
<td>*=</td>
<td>x *= y</td>
<td>x = x * y</td>
</tr>
<tr>
<td>/=</td>
<td>x /= y</td>
<td>x = x / y</td>
</tr>
<tr>
<td>%=</td>
<td>x %= y</td>
<td>x = x % y</td>
</tr>
</tbody>
</table>
Assignment Operators

The right hand side of an assignment operator can be a complex expression

The entire right-hand expression is evaluated first, then the result is combined with the original variable

Therefore

\[
\text{result} /= (\text{total}-\text{MIN}) \mod \text{num};
\]

is equivalent to

\[
\text{result} = \text{result} / ((\text{total}-\text{MIN}) \mod \text{num});
\]
Assignment Operators

The behavior of some assignment operators depends on the types of the operands.

If the operands to the `+=` operator are strings, the assignment operator performs string concatenation.

The behavior of an assignment operator (`+=`) is always consistent with the behavior of the corresponding operator (`+`).
Data Conversions

Sometimes it is convenient to convert data from one type to another

For example, in a particular situation we may want to treat an integer as a floating point value

These conversions do not change the type of a variable or the value that's stored in it – they only convert a value as part of a computation
Data Conversions

Conversions must be handled carefully to avoid losing information.

*Widening conversions* are safest because they tend to go from a small data type to a larger one (such as a `short` to an `int`).

*Narrowing conversions* can lose information because they tend to go from a large data type to a smaller one.

In Java, data conversions can occur in three ways:
- assignment conversion
- promotion
- casting
# Data Conversions

## Widening Conversions

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>short, int, long, float, or double</td>
</tr>
<tr>
<td>short</td>
<td>int, long, float, or double</td>
</tr>
<tr>
<td>char</td>
<td>int, long, float, or double</td>
</tr>
<tr>
<td>int</td>
<td>long, float, or double</td>
</tr>
<tr>
<td>long</td>
<td>float or double</td>
</tr>
<tr>
<td>float</td>
<td>double</td>
</tr>
</tbody>
</table>

## Narrowing Conversions

<table>
<thead>
<tr>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td>byte</td>
<td>char</td>
</tr>
<tr>
<td>short</td>
<td>byte or char</td>
</tr>
<tr>
<td>char</td>
<td>byte or short</td>
</tr>
<tr>
<td>int</td>
<td>byte, short, or char</td>
</tr>
<tr>
<td>long</td>
<td>byte, short, char, or int</td>
</tr>
<tr>
<td>float</td>
<td>byte, short, char, int, or long</td>
</tr>
<tr>
<td>double</td>
<td>byte, short, char, int, long, or float</td>
</tr>
</tbody>
</table>
Assignment Conversion

*Assignment conversion* occurs when a value of one type is assigned to a variable of another.

If `money` is a `float` variable and `dollars` is an `int` variable, the following assignment converts the value in `dollars` to a `float`:

```
money = dollars
```

Only widening conversions can happen via assignment.

Note that the value or type of `dollars` did not change.
Promotion

Promotion happens automatically when operators in expressions convert their operands.

For example, if `sum` is a float and `count` is an int, the value of `count` is converted to a floating point value to perform the following calculation:

```
result = sum / count;
```
Casting is the most powerful, and dangerous, technique for conversion. Both widening and narrowing conversions can be accomplished by explicitly casting a value. To cast, the type is put in parentheses in front of the value being converted.

For example, if `total` and `count` are integers, but we want a floating point result when dividing them, we can cast `total` as follows:

```
result = (float) total / count;
```
Key Things to take away:

• The print and println methods are two services provided by the System.out object
• In Java, the + operator is used both for addition and for string concatenation
• An escape character can be used to represent a character that would otherwise cause a compile error
• A variable is a name for a memory location used to hold a value of a particular data type
• Accessing data leaves them intact in memory, but an assignment statement overwrites old data
• One cannot assign a value of one type to a variable of an incompatible type
• Constants hold a particular value for the duration of their existence
• Java has two types of numeric values: integer and floating point. There are four integer data types and two floating point data types
• Java using 16-bit Unicode character set to represent character data
• Expressions are combinations of operators and operands used to perform a calculation
• The type of result produced by arithmetic division depends on the types of the operands
• Java follows a well-defined set of precedence rules that governs the order in which operators will be evaluated in an expression
• Narrowing conversions should be avoided because they can lose information
