Chapter 5 Link Layer and LANs

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

5.6 Link-layer switches
5.7 PPP
5.8 Link virtualization: MPLS
5.9 A day in the life of a web request

Link Layer: Introduction

Terminology:

- hosts and routers are nodes
- communication channels that connect adjacent nodes along communication path are links
 - wired links
 - wireless links
 - LANs
- layer-2 packet is a frame, encapsulates datagram

data-link layer has responsibility of transferring datagram from one node to *physically adjacent* node over a link

Link layer: context

- datagram transferred by different link protocols over different links:
 - e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- each link protocol provides different services
 - e.g., may or may not provide rdt over link

transportation analogy

- trip from Princeton to Lausanne
 - limo: Princeton to JFK
 - plane: JFK to Geneva
 - train: Geneva to Lausanne
- tourist = datagram
- transport segment = communication link
- transportation mode = link layer protocol
- travel agent = routing algorithm

Link Layer Services

- framing, link access:
 - encapsulate datagram into frame, adding header, trailer
 - channel access if shared medium
 - "MAC" addresses used in frame headers to identify source, dest
 - different from IP address!
- reliable delivery between adjacent nodes
 - we learned how to do this already (chapter 3)!
 - seldom used on low bit-error link (fiber, some twisted pair)
 - wireless links: high error rates
 - Q: why both link-level and end-end reliability?

Link Layer Services (more)

- * flow control:
 - pacing between adjacent sending and receiving nodes
- error detection:
 - errors caused by signal attenuation, noise.
 - receiver detects presence of errors:
 - signals sender for retransmission or drops frame
- error correction:
 - receiver identifies and corrects bit error(s) without resorting to retransmission
- half-duplex and full-duplex
 - with half duplex, nodes at both ends of link can transmit, but not at same time

Where is the link layer implemented?

- in each and every host
- link layer implemented in "adaptor" (*network interface card* NIC)
 - Ethernet card, PCMCI card, 802.11 card
 - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

Adaptors Communicating

- sending side:
 - encapsulates datagram in frame
 - adds error checking bits, rdt, flow control, etc.

- receiving side
 - looks for errors, rdt, flow control, etc
 - extracts datagram, passes to upper layer at receiving side

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

5.6 Link-layer switches
5.7 PPP
5.8 Link virtualization: MPLS
5.9 A day in the life of a web request

Error Detection

EDC= Error Detection and Correction bits (redundancy)

- D = Data protected by error checking, may include header fields
- Error detection not 100% reliable!
 - protocol may miss some errors, but rarely
 - larger EDC field yields better detection and correction

Parity Checking

Single Bit Parity: Detect single bit errors

Two Dimensional Bit Parity: Detect and correct single bit errors

Internet checksum (review)

<u>Goal:</u> detect "errors" (e.g., flipped bits) in transmitted packet (note: used at transport layer *only*)

Sender:

- treat segment contents as sequence of 16-bit integers
- checksum: addition (1's complement sum) of segment contents
- sender puts checksum value into UDP checksum field

Receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
 - NO error detected
 - YES no error detected. But maybe errors nonetheless?

Checksumming: Cyclic Redundancy Check

- view data bits, D, as a binary number
- choose r+1 bit pattern (generator), G
- goal: choose r CRC bits, R, such that
 - <D,R> exactly divisible by G (modulo 2)
 - receiver knows G, divides <D,R> by G. If non-zero remainder: error detected!
 - can detect all burst errors less than r+1 bits
- widely used in practice (Ethernet, 802.11 WiFi, ATM)

$$\leftarrow d \text{ bits} \longrightarrow \leftarrow r \text{ bits} \longrightarrow \qquad bit$$

$$D: \text{ data bits to be sent } R: CRC \text{ bits} \qquad pattern$$

$$D*2^{r} XOR R \qquad mathematical formula$$

CRC Example

Want:

 $D^{2^{r}} XOR R = nG$

equivalently:

 $D^{2^{r}} = nG XOR R$

equivalently:

if we divide D^{2^r} by G, want remainder R

$$R = remainder \begin{bmatrix} D \cdot 2^r \\ G \end{bmatrix}$$

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3 Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

5.6 Link-layer switches
5.7 PPP
5.8 Link virtualization: MPLS
5.9 A day in the life of a web request

Multiple Access Links and Protocols

Two types of "links":

- point-to-point
 - PPP for dial-up access
 - point-to-point link between Ethernet switch and host
- broadcast (shared wire or medium)
 - old-fashioned Ethernet
 - upstream HFC
 - 802.11 wireless LAN

shared wire (e.g., cabled Ethernet)

shared RF (satellite)

humans at a cocktail party (shared air, acoustical)

Multiple Access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
 - collision if node receives two or more signals at the same time

multiple access protocol

- distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
 - no out-of-band channel for coordination

Ideal Multiple Access Protocol

Broadcast channel of rate R bps

- 1. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
 - no special node to coordinate transmissions
 - no synchronization of clocks, slots
- 4. simple

MAC Protocols: a taxonomy

Three broad classes:

- Channel Partitioning
 - divide channel into smaller "pieces" (time slots, frequency, code)
 - allocate piece to node for exclusive use
- Random Access
 - channel not divided, allow collisions
 - "recover" from collisions
- "Taking turns"
 - nodes take turns, but nodes with more to send can take longer turns

Channel Partitioning MAC protocols: TDMA

TDMA: time division multiple access

- access to channel in "rounds"
- each station gets fixed length slot (length = pkt trans time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle

Channel Partitioning MAC protocols: FDMA

- FDMA: frequency division multiple access
- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

Random Access Protocols

- When node has packet to send
 - transmit at full channel data rate R.
 - no *a priori* coordination among nodes
- * two or more transmitting nodes \rightarrow "collision",
- random access MAC protocol specifies:
 - how to detect collisions
 - how to recover from collisions (e.g., via delayed retransmissions)
- Examples of random access MAC protocols:
 - slotted ALOHA
 - ALOHA
 - CSMA, CSMA/CD, CSMA/CA

Slotted ALOHA

Assumptions:

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

Slotted ALOHA

Assumptions:

- * all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

<u>Operation:</u>

- when node obtains fresh frame, transmits in next slot
 - *if no collision:* node can send new frame in next slot
 - *if collision:* node retransmits frame in each subsequent slot with prob. p until success

Slotted ALOHA

<u>Pros</u>

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

<u>Cons</u>

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

Slotted Aloha efficiency

Efficiency : long-run fraction of successful slots (many nodes, all with many frames to send)

- suppose: N nodes with many frames to send, each transmits in slot with probability p
- prob that given node has success in a slot = p(1-p)^{№1}
- In prob that any node has a success = Np(1-p)^{№1}

- max efficiency: find p* that maximizes Np(1-p)^{№1}
- ★ for many nodes, take limit of Np*(1-p*)^{№1}as N goes to infinity, gives:

Max efficiency = 1/e = .37

At best: channel used for useful transmissions 37% of time!

Pure (unslotted) ALOHA

- unslotted Aloha: simpler, no synchronization
- when frame first arrives
 - transmit immediately
- collision probability increases:
 - frame sent at t_0 collides with other frames sent in $[t_0-1,t_0+1]$

Pure Aloha efficiency

P(success by given node) = P(node transmits).

P(no other node transmits in $[p_0-1,p_0]$ · P(no other node transmits in $[p_0,p_0+1]$ = $p \cdot (1-p)^{N-1} \cdot (1-p)^{N-1}$

 $= p \cdot (1-p)^{2(N-1)}$

 \dots choosing optimum p and then letting n -> infty \dots

even worsethalf slotted Aloha!

CSMA (Carrier Sense Multiple Access)

<u>CSMA</u>: listen before transmit:

If channel sensed idle: transmit entire frame

If channel sensed busy, defer transmission

human analogy: don't interrupt others!

CSMA collisions

collisions can still occur:

propagation delay means two nodes may not hear each other's transmission

collision:

entire packet transmission time wasted

note:

role of distance & propagation delay in determining collision probability spatial layout of nodes

CSMA/CD (Collision Detection)

CSMA/CD: carrier sensing, deferral as in CSMA

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection:
 - easy in wired LANs: measure signal strengths, compare transmitted, received signals
 - difficult in wireless LANs: received signal strength overwhelmed by local transmission strength

human analogy: the polite conversationalist

CSMA/CD collision detection

channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead
- "taking turns" protocols

look for best of both worlds!

Polling:

- master node "invites" slave nodes to transmit in turn
- typically used with
 "dumb" slave devices
- concerns:
 - polling overhead
 - Iatency
 - single point of failure (master)

Token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - Iatency
 - single point of failure (token)

Token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - Iatency
 - single point of failure (token)

Token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - Iatency
 - single point of failure (token)

Summary of MAC protocols

- * *channel partitioning,* by time, frequency or code
 - Time Division, Frequency Division
- * random access (dynamic),
 - ALOHA, S-ALOHA, CSMA, CSMA/CD
 - carrier sensing: easy in some technologies (wire), hard in others (wireless)
 - CSMA/CD used in Ethernet
 - CSMA/CA used in 802.11
- taking turns
 - polling from central site, token passing
 - Bluetooth, FDDI, IBM Token Ring

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

5.6 Link-layer switches
5.7 PPP
5.8 Link virtualization: MPLS
5.9 A day in the life of a web request

MAC Addresses and ARP

- 32-bit IP address:
 - network-layer address
 - used to get datagram to destination IP subnet
- MAC (or LAN or physical or Ethernet) address:
 - function: get frame from one interface to another physically-connected interface (same network)
 - 48 bit MAC address (for most LANs)
 - burned in NIC ROM, also sometimes software settable

LAN Addresses and ARP

Each adapter on LAN has unique LAN address

LAN Address (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
 - (a) MAC address: like Social Security Number
 - (b) IP address: like postal address
- * MAC flat address \rightarrow portability
 - can move LAN card from one LAN to another
- IP hierarchical address NOT portable
 - address depends on IP subnet to which node is attached

ARP: Address Resolution Protocol

<u>*Question:*</u> how to determine MAC address of B knowing B's IP address?

- Each IP node (host, router) on LAN has ARP table
- ARP table: IP/MAC address mappings for some LAN nodes

< IP address; MAC address; TTL>

 TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

ARP protocol: Same LAN (network)

- A wants to send datagram to B, and B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
 - dest MAC address = FF-FF-FF-FF-FF
 - all machines on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
 - frame sent to A's MAC address (unicast)

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
 - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
 - nodes create their ARP tables without intervention from net administrator

ARP protocol: Same LAN (network)

- A wants to send datagram to B, and B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
 - dest MAC address = FF-FF-FF-FF-FF
 - all machines on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
 - frame sent to A's MAC address (unicast)

walkthrough: send datagram from A to B via R.

- focus on addressing at both IP (datagram) and MAC layer (frame)
- assume A knows B's IP address
- assume A knows B's MAC address (how?)
- assume A knows IP address of first hop router, R (how?)
- assume A knows MAC address of first hop router interface (how?)

✤ A creates IP datagram with IP source A, destination B

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame with R's MAC address as dest, frame contains A-to-B IP datagram

frame sent from A to R

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram

- R forwards datagram with IP source A, destination B
- R creates link-layer frame with B's MAC address as dest, frame contains A-to-B IP datagram
