• Hidden Markov Models (HMMs)
  – Distinction between Markov Chains and HMMs
  – Application of HMMs to Part of Speech tagging
  – Algorithms for HMMs: Viterbi decoding and the Forward-Backward Algorithm (Baum-Welch)
Trigram Models

- $P(w_{1,2,...,m}) = P(w_1) \times P(w_2 \mid w_1) \times P(w_3 \mid w_{1,2}) \times P(w_4 \mid w_{1,3}) \times \ldots$

- $P(w_k \mid w_{1,k-1}) = P(w_k \mid w_{k-n-1,k-1})$

- hence the name $n$-grams; $n = 2$: bigrams, $n = 3$: trigrams

- also possible to define variable length $n$-grams

- Best performing language model when used with smoothing
Trigram Models and Markov Chains

Trigram Models and Smoothing

• Let vocabulary be $V$

• worst case size of a trigram model: $|V|$; for a given corpus: $|V|$?

• $P(w_n \mid w_{n-2,n-1}) =$$\lambda_1(w_{n-2,n-1})Pe(w_n) + \lambda_2(w_{n-2,n-1})Pe(w_n \mid w_{n-1}) +$$\lambda_3(w_{n-2,n-1})Pe(w_n \mid w_{n-2,n-1})$

• $\lambda_1(w_{n-2,n-1}) + \lambda_2(w_{n-2,n-1}) + \lambda_3(w_{n-2,n-1}) = 1$
Trigram Models

- Using cross-entropy as a model evaluator

- Removing the "correct" model from the equation was possible when the model was ergodic

- Samples (when large enough) correspond to the true probabilities in the model

- Also, the model has to be stationary: for our purposes, it means that the values for a given context do not vary
Trigram Models: A Generative Model

Part of Speech Tagging using Trigram Models

- $P(w_{1,n}) = \sum_{t_{1,n+1}} P(w_{1,n}, t_{1,n+1})$

- $\arg\max_{t_{1,n+1}} P(t_{1,n+1} \mid w_{1,n}) = \arg\max_{t_{1,n+1}} \frac{P(w_{1,n}, t_{1,n+1})}{P(w_{1,n})}$

- $\arg\max_{t_{1,n+1}} P(w_{1,n}, t_{1,n+1})$
Hidden Markov Models

- A set of states, each state is hidden, i.e. not visible in the training data. The number of states is arbitrary and set in advance (see paper by A. Stolcke and S. M. Omohundro)

- Assume each state is connected to every other state

- Numerous applications in speech, language processing, cryptography, modelling continuous fns.
Hidden Markov Models

- At each time tick $t$, we traverse from one state to another and emit an output symbol

- $P(s^i \xrightarrow{w} s^j) = P(S_{t+1} = s^j, W_t = w, | S_t = s^i)$

- $P(s^i \xrightarrow{w} s^j) = P(w, s^j | s^i) = P(w | s^i)P(s^j | s^i)$ — the Markov assumption

- transition probability: $P(s_j | s_i)$

- output probability: $P(w | s_i)$
Hidden Markov Models

- \( P(w_{1,n}) = \sum_{s_{1,n+1}} P(w_{1,n}, s_{1,n+1}) \)

- \( \sum_{s_{1,n+1}} \prod_{i=1}^{n} P(w_i, s_{i+1} | s_i) \)

- \( \sum_{s_{1,n+1}} \prod_{i=1}^{n} P(s_i \xrightarrow{w_i} s_{i+1}) \)

- **Best path (Viterbi algorithm):** \( \arg \max_{s_{1,n+1}} \prod_{i=1}^{n} P(s_i \xrightarrow{w_i} s_{i+1}) \)
Forward-Backward Algorithm: Baum-Welch

- How can we compute transition and output probabilities, when the state sequences are "hidden"

- Intuitively, probability of taking a transition from a state $s_i$ to $s_j$ is

$$P_e(s_i \xrightarrow{w} s_j) = \frac{C(s_i \xrightarrow{w} s_j)}{\sum_{k, w'} C(s_i \xrightarrow{w'} s_k)}$$

- So once we have a method for computing $C(s_i \xrightarrow{w} s_j)$ we can re-estimate each transition probability

- Note that number of times you take a transition also depends on the initial setting of the transition probability
Forward-Backward Algorithm

- Hence, the probability of a transition is the number of times it was used in a path (state sequence) times the probability of that path (for all paths)

\[ C(s^i \xrightarrow{w} s^j) = \sum_{s_{1,n+1}} P(s_{1,n+1} \mid w_{1,n}) \cdot \eta(s^i \xrightarrow{w} s^j, s_{1,n+1}, w_{1,n}) \]

- \( \eta \) counts number of times \( s^i \xrightarrow{w} s^j \) appears in the path \( s_{1,n+1} \) when the output is \( w_{1,n} \)
Forward-Backward Algorithm

\[
C(s^i \rightarrow s^j) = \sum_{s_{1,n+1}} P(s_{1,n+1} | w_{1,n}) \cdot \eta(s^i \rightarrow s^j, s_{1,n+1}, w_{1,n})
\]

\[
C(s^i \rightarrow s^j) = \frac{1}{P(w_{1,n})} \times \sum_{t=1}^{n} \sum_{s_{1,n+1}} P(s_{1,n+1}, w_{1,n}, S_t = s^i, S_{t+1} = s^j, W_t = w)
\]

\[
P(w_{1,n}) = \sum_{s_{1,n+1}} P(s_{1,n+1}, w_{1,n})
\]
\[ C(s^i \rightarrow s^j) = \frac{1}{P(w_{1,n})} \times \]
\[ \sum_{t=1}^{n} P(w_{1,n}, S_t = s^i, S_{t+1} = s^j, W_t = w) \]
\[ = \frac{1}{P(w_{1,n})} \times \]
\[ \sum_{t=1}^{n} P(w_{1,t-1}, S_t = s^i, S_{t+1} = s^j, W_t = w, w_{t+1,n}) \]
\[ = \frac{1}{P(w_{1,n})} \times \sum_{t=1}^{n} P(w_{1,t-1}, S_t = s^i) \cdot \]
\[ P(S_{t+1} = s^j, W_t = w \mid w_{1,t-1}, S_t = s^i) \cdot \]
\[ P(w_{t+1,n} \mid w_{1,t}, S_t = s^i, S_{t+1} = s^j) \]
Forward-Backward Algorithm

\[ C(s^i \xrightarrow{w} s^j) = \frac{1}{P(w_{1,n})} \times \sum_{t=1}^{n} P(w_{1,t-1}, S_t = s^i) \cdot P(S_{t+1} = s^j, W_t = w | w_{1,t-1}, S_t = s^i) \cdot P(w_{t+1,n} | w_{1,t}, S_t = s^i, S_{t+1} = s^j) \]

\[ = \frac{1}{P(w_{1,n})} \times \sum_{t=1}^{n} P(w_{1,t-1}, S_t = s^i) \cdot P(S_{t+1} = s^j, W_t = w | S_t = s^i) \cdot P(w_{t+1,n} | S_{t+1} = s^j) \]

\[ = \frac{1}{P(w_{1,n})} \times \sum_{t=1}^{n} \alpha_i(t) \cdot P(s^i \xrightarrow{w} s^j) \cdot \beta_j(t + 1) \]
Forward-Backward Algorithm

\[ \alpha_i(t) = P(w_{1,t-1}, S_t = s^i) \]
\[ \alpha_{s_1}(1) = 1.0 \]
\[ \alpha_j(t + 1) = P(w_{1,t}, S_{t+1} = s^j) \]
\[ = \sum_i P(w_{1,t}, S_t = s^i, S_{t+1} = s^j) \]
\[ = \sum_i P(w_{1,t-1}, S_t = s^i) \cdot P(W_t = w, S_{t+1} = s^j \mid w_{1,t-1}, S_t = s^i) \]
\[ = \sum_i \alpha_i(t) \cdot P(s^i \xrightarrow{w} s^j) \]
Forward-Backward Algorithm

\[ \beta_i(t) = P(w_{t,n} \mid S_t = s^i) \]

\[ \beta_i(n + 1) = P(\epsilon \mid S_{n+1} = s^i) = 1.0 \]

\[ \beta_i(t - 1) = P(w_{t-1,n} \mid S_{t-1} = s^i) \]

\[ = \sum_j P(W_{t-1} = w, S_t = s^j \mid S_{t-1} = s^i) \cdot P(w_{t,n} \mid W_{t-1} = w, S_t = s^j, S_{t-1} = s^i) \]

\[ = \sum_j P(W_{t-1} = w, S_t = s^j \mid S_{t-1} = s^i) \cdot P(w_{t,n} \mid S_t = s^j) \]

\[ = \sum_j P(s^i \xrightarrow{w} s^j) \cdot \beta_j(t) \]
\[ \alpha_k(t-1) \]

\[ P(s_k w \rightarrow s_i) \]

\[ \alpha_i(t) P(s_i w \rightarrow s_j) \beta_j(t+1) \]

\[ \beta_m(t+2) \]

\[ \alpha_i(t) = \sum_{k=1}^{\mid Q \mid} \alpha_k(t-1) P(s_k w \rightarrow s_i) \]

\[ \beta_j(t+1) = \sum_{m=1}^{\mid Q \mid} P(s_j w \rightarrow s_m) \beta_m(t+2) \]

\[ C(s_i w \rightarrow s_j) = \frac{1}{P(w_{1,n})} \sum_{t=1}^{n} \alpha_i(t) P(s_i w \rightarrow s_j) \beta_j(t+1) \]
\[ \alpha_q(t) = \alpha_q(t - 1)P(a, q \mid q) + \alpha_q(t - 1)P(b, q \mid q) + \alpha_r(t - 1)P(a, q \mid r) + \alpha_r(t - 1)P(b, q \mid r) \]

\[ \beta_r(t + 1) = P(a, q \mid r)\beta_q(t + 2) + P(b, q \mid r)\beta_q(t + 2) + P(a, r \mid r)\beta_r(t + 2) + P(b, r \mid r)\beta_r(t + 2) \]

\[ C(q \xrightarrow{a} r) = \frac{1}{P(w_{1,n})} \sum_{t=1}^{n} \alpha_q(t)P(a, r \mid q)\beta_r(t + 1) \]
Forward-Backward Algorithm

- Set initial transition probabilities to appropriate values (usually random)

- Compute $C(s^i \xrightarrow{w} s^j)$ for each state $i$ and then

$$P_e(s^i \xrightarrow{w} s^j) = \frac{C(s^i \xrightarrow{w} s^j)}{\sum_{k,w'} C(s^i \xrightarrow{w'} s^k)}$$

- Compute likelihood $P(w_{1,n}) = \beta_{s1}(1)$; iterate until likelihood is maximized (or entropy is minimized)

- Here we considered the case for one training sentence $w_{1,n}$. For a whole corpus, $\prod_k P(w_{1,n}^k)$ is the likelihood of the entire corpus with $k$ sentences
Forward-Backward Algorithm

- Likelihood is guaranteed to be non-decreasing due to the theorem by Baum (generalized by Dempster, Laird and Rubin)

- Forward-Backward Algorithm is an example of purely unsupervised learning

- Applications of the Forward-Backward Algorithm
Next Time

- Using the Forward-Backward Algorithm to decrease human supervision
