Kernel Methods and Support Vector Machines Oliver Schulte - CMPT 726

Bishop PRML Ch. 6

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Support Vector Machines

Defining Characteristics

- Like logistic regression, good for continuous input features, discrete target variable.
- Like nearest neighbor, a *kernel method*: classification is based on weighted similar instances. The kernel defines similarity measure.
- Sparsity: Tries to find a few important instances, the *support vectors*.
- Intuition: Netflix recommendation system.

SVMs: Pros and Cons

Pros

- Very good classification performance, basically unbeatable.
- Fast and scaleable learning.
- Pretty fast inference.

Cons

- No model is built, therefore black-box.
- Still need to specify kernel function (like specifying basis functions).
- Issues with multiple classes, can use probabilistic version. (Relevance Vector Machine).

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Linear Classification Revisited

- Consider a two class classification problem
- Use a linear model

$$y(\boldsymbol{x}) = \boldsymbol{w} \bullet \boldsymbol{x} + b$$

followed by a threshold function

- For now, let's assume training data are linearly separable (possibly after mapping to higher-dimensional space).
 - Recall that the perceptron would converge to a perfect classifier for such data
 - But there are many such perfect classifiers

Max Margin Classifiers

- We can define the margin of a classifier as the minimum distance to any example
- In support vector machines the decision boundary which maximizes the margin is chosen.
- Intuitively, this is the line "right in the middle" between the two classes.

Support Vectors

- The support vectors are the points at minimum distance to the decision boundary.
- The max-margin boundary depends only on the support vectors: other data points do not matter for classification and need not be stored.

Example: X-OR

- X-OR problem: class of (x_1, x_2) is positive iff $x_1 \cdot x_2 > 0$.
- Not linearly separable in input space, but linearly separable if *we add extra dimensions.*

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- Use 6 basis functions $\phi(x_1, x_2) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$
- Simple classifier $y(x_1, x_2) = \phi_5(x_1, x_2) = \sqrt{2}x_1x_2$.
 - *Linear* in basis function space.

Example: X-OR

- X-OR problem: class of (x_1, x_2) is positive iff $x_1 \cdot x_2 > 0$.
- Not linearly separable in input space, but linearly separable if *we add extra dimensions.*

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

- Use 6 basis functions $\phi(x_1, x_2) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$
- Simple classifier $y(x_1, x_2) = \phi_5(x_1, x_2) = \sqrt{2}x_1x_2$.
 - *Linear* in basis function space.

Linear Separability Example

3-D mapping $(x_1^2, x_{27}^2 \sqrt{2a_1x_2}) \rightarrow (a)$

Linear Separability Example

3-D mapping $(x_1^2, x_2^2, \sqrt{2x_1x_2})$ $\rightarrow 4$ $\rightarrow \infty$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

The Kernel Trick

- There can be many extra dimensions, even infinite (see assignment).
 - Don't want to compute basis function mapping $\phi(\mathbf{x})$.
- Key insight 1: Linear classification requires *only the dot product*.
- Key insight 2: The high-dimensional dot product
 φ(x) φ(z) can often be computed as a kernel function of the input vectors only:

$$\boldsymbol{\phi}(\boldsymbol{x}) \bullet \boldsymbol{\phi}(\boldsymbol{z}) = k(\boldsymbol{x}, \boldsymbol{z}).$$

Theoretical View User View Building Kernels Computing the Max-Margin Classifier

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Kernel Trick Example

- Consider again the X-OR 6 basis functions $\phi(x_1, x_2) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$
- Exercise: find a closed form expression for $\phi(x) \bullet \phi(z)$
- Solution: Dot product $\phi(\mathbf{x}) \bullet \phi(\mathbf{z}) = (1 + \mathbf{x} \bullet \mathbf{z})^2 = k(\mathbf{x}, \mathbf{z})$.
- A quadratic kernel.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Kernel Trick Example

- Consider again the X-OR 6 basis functions $\phi(x_1, x_2) = (1, \sqrt{2}x_1, \sqrt{2}x_2, x_1^2, \sqrt{2}x_1x_2, x_2^2).$
- Exercise: find a closed form expression for $\phi(x) \bullet \phi(z)$
- Solution: Dot product $\phi(\mathbf{x}) \bullet \phi(z) = (1 + \mathbf{x} \bullet z)^2 = k(\mathbf{x}, z)$.
- A quadratic kernel.

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

The Kernel Classification Formula

- Suppose we have a kernel function *k* and *N* labelled instances with weights *a_n* ≥ 0, *n* = 1,...,*N*.
- As with the perceptron, the target labels +1 are for positive class, -1 for negative class.

Then

$$y(\mathbf{x}) = \sum_{n=1}^{N} a_n t_n k(\mathbf{x}, \mathbf{x}_n) + b$$

- x is classified as positive if y(x) > 0, negative otherwise.
- If $a_n > 0$, then x_n is a support vector.
- Don't need to store other vectors.
- a will be sparse many zeros.

Theoretical View

Non-Separable Data

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

- SVM with Gaussian kernel
- Support vectors circled.
- They are the closest to the other class.
- Note non-linear decision boundary in x space

• From Burges, A Tutorial on Support Vector Machines for Pattern Recognition (1998)

SVM trained using cubic polynomial kernel

 $k(x_1, x_2) = (x_1 \bullet x_2 + 1)^3$

- Left is linearly separable
 - Note decision boundary is almost linear, even using cubic polynomial kernel
- Right is not linearly separable
 - But is separable using polynomial kernel

Learning the Instance Weights

- The max-margin classifier is found by solving the following problem:
- Maximize wrt a

$$\tilde{L}(\boldsymbol{a}) = \sum_{n=1}^{N} a_n - \frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} a_n a_m t_n t_m k(\boldsymbol{x}_n, \boldsymbol{x}_m)$$

subject to the constraints

•
$$a_n \geq 0, n = 1, \ldots, N$$

•
$$\sum_{n=1}^{n} a_n t_n = 0$$

- It is quadratic, with linear constraints, convex in a
- Optimal *a* can be found
 - With large datasets, local search strategies employed

let's check SVM demo http://svm.dcs.rhbnc.ac.uk/pagesnew/GPat.shtml

Valid Kernels

- Valid kernels: if $k(\cdot, \cdot)$ satisfies:
 - Symmetric; $k(\mathbf{x}_i, \mathbf{x}_j) = k(\mathbf{x}_j, \mathbf{x}_i)$
 - Positive definite; for any x_1, \ldots, x_N , the Gram matrix *K* must be positive semi-definite:

$$\boldsymbol{K} = \begin{pmatrix} k(\boldsymbol{x}_1, \boldsymbol{x}_1) & k(\boldsymbol{x}_1, \boldsymbol{x}_2) & \dots & k(\boldsymbol{x}_1, \boldsymbol{x}_N) \\ \vdots & \vdots & \ddots & \vdots \\ k(\boldsymbol{x}_N, \boldsymbol{x}_1) & k(\boldsymbol{x}_N, \boldsymbol{x}_2) & \dots & k(\boldsymbol{x}_N, \boldsymbol{x}_N) \end{pmatrix}$$

• Positive semi-definite means $x \bullet Kx \ge 0$ for all x (like metric) then $k(\cdot, \cdot)$ corresponds to a dot product in some space ϕ

- a.k.a. Mercer kernel, admissible kernel, reproducing kernel
- Theorem of Mercer's 1909!

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Examples of Kernels

- Some kernels:
 - Linear kernel $k(\mathbf{x}_1, \mathbf{x}_2) = \mathbf{x}_1 \bullet \mathbf{x}_2$
 - Polynomial kernel $k(\mathbf{x}_1, \mathbf{x}_2) = (1 + \mathbf{x}_1 \bullet \mathbf{x}_2)^d$
 - Contains all polynomial terms up to degree d
 - Gaussian kernel $k(x_1, x_2) = \exp(-||x_1 x_2||^2/2\sigma^2)$
 - Infinite dimension feature space

Constructing Kernels

• Can build new valid kernels from existing valid ones:

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

•
$$k(x_1, x_2) = ck_1(x_1, x_2), c > 0$$

•
$$k(x_1, x_2) = k_1(x_1, x_2) + k_2(x_1, x_2)$$

•
$$k(x_1, x_2) = k_1(x_1, x_2)k_2(x_1, x_2)$$

•
$$k(x_1, x_2) = \exp(k_1(x_1, x_2))$$

Table on p. 296 gives many such rules

Theoretical View

・ロト ・ 同 ・ ・ ヨ ・ ・ ヨ ・ うへつ

More Kernels

- Stationary kernels are only a function of the difference between arguments: k(x1, x2) = k(x1 - x2)
 - Translation invariant in input space: $k(\mathbf{x}_1, \mathbf{x}_2) = k(\mathbf{x}_1 + \mathbf{c}, \mathbf{x}_2 + \mathbf{c})$
- Homogeneous kernels, a. k. a. radial basis functions only a function of magnitude of difference: $k(x_1, x_2) = k(||x_1 x_2||)$
- Set subsets $k(A_1, A_2) = 2^{|A_1 \cap A_2|}$, where |A| denotes number of elements in A
- Domain-specific: think hard about your problem, figure out what it means to be similar, define as k(·, ·), prove positive definite.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

Marginal Geometry

- See assignment.
- Projection of x in w dir. is $\frac{w \cdot x}{||w||}$
- $y(\mathbf{x}) = 0$ when $\mathbf{w} \bullet \mathbf{x} = -b$, or $\frac{\mathbf{w} \bullet \mathbf{x}}{||\mathbf{w}||} = \frac{-b}{||\mathbf{w}||}$
- So $\frac{w \cdot x}{||w||} \frac{-b}{||w||} = \frac{y(x)}{||w||}$ is signed distance to decision boundary

Support Vectors

- Assuming data are separated by the hyperplane, distance to decision boundary is $\frac{t_n y(\mathbf{x}_n)}{||\mathbf{w}||}$
- The maximum margin criterion chooses *w*, *b* by:

$$\arg\max_{\boldsymbol{w},b}\left\{\frac{1}{||\boldsymbol{w}||}\min_{n}[t_{n}(\boldsymbol{w} \bullet \boldsymbol{x}_{n}+b)]\right\}$$

Points with this min value are known as support vectors

• This optimization problem is complex:

$$\arg\max_{\boldsymbol{w},b}\left\{\frac{1}{||\boldsymbol{w}||}\min_{n}[t_{n}(\boldsymbol{w} \bullet \boldsymbol{x}_{n})+b)]\right\}$$

- Exercise: Prove that rescaling $w \to \kappa w$ and $b \to \kappa b$ does not change distance $\frac{t_n y(x_n)}{||w||}$ (many equiv. answers)
- So for *x*_{*} closest to surface, can set (how?):

$$t_*(\boldsymbol{w} \bullet \boldsymbol{x}_* + b) = 1$$

• All other points are at least this far away:

$$\forall n , t_n(w \bullet x_n + b) \geq 1$$

$$\arg\max_{w,b} \frac{1}{||w||} = \arg\min_{w,b} \frac{1}{2} ||w||^2$$

• This optimization problem is complex:

$$\arg\max_{\boldsymbol{w},b}\left\{\frac{1}{||\boldsymbol{w}||}\min_{n}[t_{n}(\boldsymbol{w}\boldsymbol{\bullet}\boldsymbol{x}_{n})+b)]\right\}$$

- Exercise: Prove that rescaling $w \to \kappa w$ and $b \to \kappa b$ does not change distance $\frac{t_n y(\mathbf{x}_n)}{||w||}$ (many equiv. answers)
- So for x_{*} closest to surface, can set (how?):

$$t_*(\boldsymbol{w} \bullet \boldsymbol{x}_* + \boldsymbol{b}) = 1$$

• All other points are at least this far away:

$$\forall n , t_n(w \bullet x_n + b) \geq 1$$

$$\arg\max_{w,b} \frac{1}{||w||} = \arg\min_{w,b} \frac{1}{2} ||w||^2$$

• This optimization problem is complex:

$$\arg\max_{\boldsymbol{w},b}\left\{\frac{1}{||\boldsymbol{w}||}\min_{n}[t_{n}(\boldsymbol{w} \bullet \boldsymbol{x}_{n})+b)]\right\}$$

- Exercise: Prove that rescaling $w \to \kappa w$ and $b \to \kappa b$ does not change distance $\frac{t_n y(x_n)}{||w||}$ (many equiv. answers)
- So for *x*_{*} closest to surface, can set (how?):

$$t_*(\boldsymbol{w} \bullet \boldsymbol{x}_* + b) = 1$$

• All other points are at least this far away:

$$\forall n$$
, $t_n(\mathbf{w} \bullet \mathbf{x}_n + b) \geq 1$

$$\arg\max_{w,b}\frac{1}{||w||} = \arg\min_{w,b}\frac{1}{2}||w||^2$$

• This optimization problem is complex:

$$\arg\max_{\boldsymbol{w},b}\left\{\frac{1}{||\boldsymbol{w}||}\min_{n}[t_{n}(\boldsymbol{w} \bullet \boldsymbol{x}_{n})+b)]\right\}$$

- Exercise: Prove that rescaling *w* → *κw* and *b* → *κb* does not change distance <sup>*t_ny(x_n)*/_{||*w*||} (many equiv. answers)
 </sup>
- So for *x*_{*} closest to surface, can set (how?):

$$t_*(\boldsymbol{w} \bullet \boldsymbol{x}_* + b) = 1$$

• All other points are at least this far away:

$$\forall n , t_n(\mathbf{w} \bullet \mathbf{x}_n + b) \geq 1$$

$$\arg\max_{\boldsymbol{w},b}\frac{1}{||\boldsymbol{w}||} = \arg\min_{\boldsymbol{w},b}\frac{1}{2}||\boldsymbol{w}||^2$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Canonical Representation

So the optimization problem is now a constrained optimization problem:

$$\arg\min_{\boldsymbol{w},b} \frac{1}{2} ||\boldsymbol{w}||^2$$

s.t. $\forall n, t_n(\boldsymbol{w} \bullet \boldsymbol{x}_n + b) \ge 1$

• To solve this, we need to use Lagrange multipliers

- $g_n(\mathbf{x}) \geq 0$
- $a_n g_n(\mathbf{x}) = 0$

Therefore $a_n = 0$ (inactive constraint) or $g_n(x) = 0$ (active constraint).

where for each n we have the KKT conditions,

- $a_n \geq 0$
- $g_n(\mathbf{x}) \geq 0$
- $a_ng_n(\mathbf{x}) = 0$

Therefore $a_n = 0$ (inactive constraint) or $g_n(\mathbf{x}) = 0$ (active constraint).

Now Where Were We

• So the optimization problem is now a constrained optimization problem:

$$\arg \min_{\boldsymbol{w}, b} \frac{||\boldsymbol{w}||^2}{2}$$

s.t. $\forall n, t_n(\boldsymbol{w} \bullet \boldsymbol{x}_n + b) \ge 1$

• For this problem, the Lagrangian (with *N* multipliers *a_n*) is:

$$L(\mathbf{w}, b, \mathbf{a}) = \frac{||\mathbf{w}||^2}{2} - \sum_{n=1}^N a_n \{ t_n(\mathbf{w} \bullet \mathbf{x}_n + b) - 1 \}$$

• We can find the derivatives of *L* wrt *w*, *b* and set to 0:

$$w = \sum_{n=1}^{N} a_n t_n \mathbf{x}_n$$
$$0 = \sum_{n=1}^{N} a_n t_n$$

The Dual Formulation

• Recall the condition:

$$\boldsymbol{w} = \sum_{n=1}^{N} a_n t_n \boldsymbol{x}_n$$

- Exercise: Show that $\frac{||\mathbf{w}||^2}{2} = \frac{1}{2} \sum_{n=1}^N \sum_{m=1}^N a_n a_m t_n t_m (\mathbf{x}_n \bullet \mathbf{x}_m).$
- Exercise: Show that

$$\sum_{n=1}^{N} a_n \{ t_n(\mathbf{w} \bullet \mathbf{x}_n + b) - 1 \} =$$

$$\sum_{n=1}^{N} \sum_{m=1}^{N} a_n a_m t_n t_m(\mathbf{x}_n \bullet \mathbf{x}_m) + b \sum_{n=1}^{N} a_n t_n - \sum_{n=1}^{N} a_n$$

◆□▶ ◆□▶ ◆豆▶ ◆豆▶ □豆 の々で

Solving The Dual Formulation

• Combining the exercise results, we obtain the dual Lagrangian as a function of the Lagrange multipliers only:

$$\tilde{L}(\boldsymbol{a}) = \sum_{n=1}^{N} a_n - \frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} a_n a_m t_n t_m (\boldsymbol{x}_n \bullet \boldsymbol{x}_m)$$

- The stationary points of *L̃* provide lower bounds on the original problem, so we want to maximize *L̃* (see http://en.wikipedia.org/wiki/Lagrange_duality).
- Apply the kernel trick to replace with kernel *k*, and remember the constraints on the Lagrange multipliers, to arrive at the following problem:
- Maximize $\tilde{L}(\boldsymbol{a}) = \sum_{n=1}^{N} a_n \frac{1}{2} \sum_{n=1}^{N} \sum_{m=1}^{N} a_n a_m t_n t_m k(\boldsymbol{x}_n, \boldsymbol{x}_m)$ subject to the constraints that

•
$$a_n \ge 0, n = 1, ..., N$$

•
$$\sum_{n=1}^{N} a_n t_n = 0$$

Theoretical View

Building Kernels

From The Dual Solution *a* to a Classifier

• Given the solution *a*, we have formulas for *w* and for *b* (omitted). Then classify as follows:

$$w = \sum_{n=1}^{N} a_n t_n \phi(\mathbf{x}_n)$$

$$y(\mathbf{x}) = w \bullet \phi(\mathbf{x}) + b = \sum_{n=1}^{N} a_n t_n k(\mathbf{x}, \mathbf{x}_n) + b$$

- Recall that every constraint is either inactive (a_n = 0) or active (a_n > 0 and t_ny(x_n) = 1).
- If $a_n > 0$, then x_n is a support vector.
- *a* will be sparse many zeros.
 - Don't need to store x_n for which $a_n = 0$

Non-Separable Data

- For most problems, data will not be linearly separable (even in feature space φ)
- Can relax the constraints from

$$t_n y(\boldsymbol{x}_n) \ge 1$$
 to $t_n y(\boldsymbol{x}_n) \ge 1 - \xi_n$

- The $\xi_n \ge 0$ are called slack variables
 - $\xi_n = 0$, satisfy original problem, so x_n is on margin or correct side of margin
 - $0 < \xi_n < 1$, inside margin, but still correctly classifed
 - $\xi_n > 1$, mis-classified

Non-Separable Data

Loss Function For Non-separable Data

 Non-zero slack variables are bad, penalize while maximizing the margin:

$$\min C \sum_{n=1}^{N} \xi_n + \frac{1}{2} ||\boldsymbol{w}||^2$$

- Constant C > 0 controls importance of large margin versus incorrect (non-zero slack)
 - Set using cross-validation
- Optimization is same quadratic, different constraints, convex

SVM Loss Function

• The SVM for the separable case solved the problem:

$$\arg\min_{\boldsymbol{w}} \frac{1}{2} ||\boldsymbol{w}||^2$$

s.t. $\forall n, t_n y_n \ge 1$

• Can write this as:

$$\arg\min_{w} \sum_{n=1}^{N} E_{\infty}(t_n y_n) + \lambda ||w||^2$$

where $E_{\infty}(z) = 0$ if $z \ge 1, \infty$ otherwise

Non-separable case relaxes this to be:

$$\arg\min_w \sum_{n=1}^N E_{SV}(t_n y_n) + \lambda ||w||^2$$
 here $E_{SV}(z) = [z]_+$ hinge loss

• $[z]_+ = z$ if $u \le 1, 0$ otherwise

where $E_{\infty}(z) = 0$ if $z \ge 1, \infty$ otherwise

Non-separable case relaxes this to be:

$$\arg\min_{\pmb{w}}\sum_{n=1}^N E_{SV}(t_ny_n) + \lambda ||\pmb{w}||^2$$
 where $E_{SV}(z) = [z]_+$ hinge loss

• $[z]_+ = z$ if $u \le 1$, 0 otherwise

- Linear classifiers, compare loss function used for learning
- $z = y_n t_n \le 0$ iff there is an error (with $t_n \in \{+1, -1\}$).
- $z = y_n t_n \ge 1$ iff the point is on the right side of the margin boundary.
 - Black is misclassification error
 - Transformed simple linear classifier, squared error: $(y_n t_n)^2$
 - Transformed logistic regression, cross-entropy error: $t_n \ln y_n$
 - SVM, hinge loss:
 - positive only if the point is on the wrong side of the margin boundary. Sparse solutions.

Two Views of Learning as Optimization

- The original SVM goal was of the form:
 - Find the simplest hypothesis that is consistent with the data, or
 - Maximize simplicity, given a consistency constraint.
- This general idea appears in much scientific model building, in image processing, and other applications.
- · Bayesian methods use a criterion of the form
 - · Find a trade-off between simplicity and data fit, or
 - Maximize sum of the type (data fit λ simplicity)
 - e.g., *ln*(*P*(*D*|*M*)) λ*ln*(*P*(*M*)) where the model prior *M* is higher for simpler models.

◆□▶ ◆□▶ ▲□▶ ▲□▶ □ のQ@

Pros and Cons of Learning Criteria

- The Bayesian approach has a solid probabilistic foundation in Bayes' theorem.
- Seems to be especially suitable for noisy data.
- The constraint-based approach is often easy for users to understand.
- Often leads to sparser simpler models.
- Suitable for "clean" data.

Conclusion

- Readings: Ch. 6.1-6.2 (pp. 291-297)
- Non-linear features, or domain-specific similarity measurements are useful
- Dot products of non-linear features, or similarity measurements, can be written as kernel functions
 - Validity by positive semi-definiteness of kernel function
- Can have algorithm work in non-linear feature space without actually mapping inputs to feature space
 - Advantageous when feature space is high-dimensional
